## ABSTRACT

Indonesia has the highest NEET rate in Southeast Asia, with 22.3% of its youth population categorized as NEET. This issue is crucial as Indonesia undergoes a demographic bonus, and ineffective utilization of this opportunity may lead to economic losses. This study examines the determinants of youth NEET status by analyzing key socio-demographic factors using data from the August 2023 National Labor Force Survey (Sakernas), which covers 158,816 individuals aged 15 to 24 across 34 provinces. Employing cross-tabulation and binary logistic regression analysis, the findings reveal that NEET youth are predominantly economically inactive. Furthermore, factors such as location of residence, gender, marital status, education level, training experience, health condition, and household size significantly influence the likelihood of youth becoming NEET in Indonesia.
